

# Introduction to Regression

## Part B: Error Evaluation and Model Comparison

CS109A Introduction to Data Science

Pavlos Protopapas

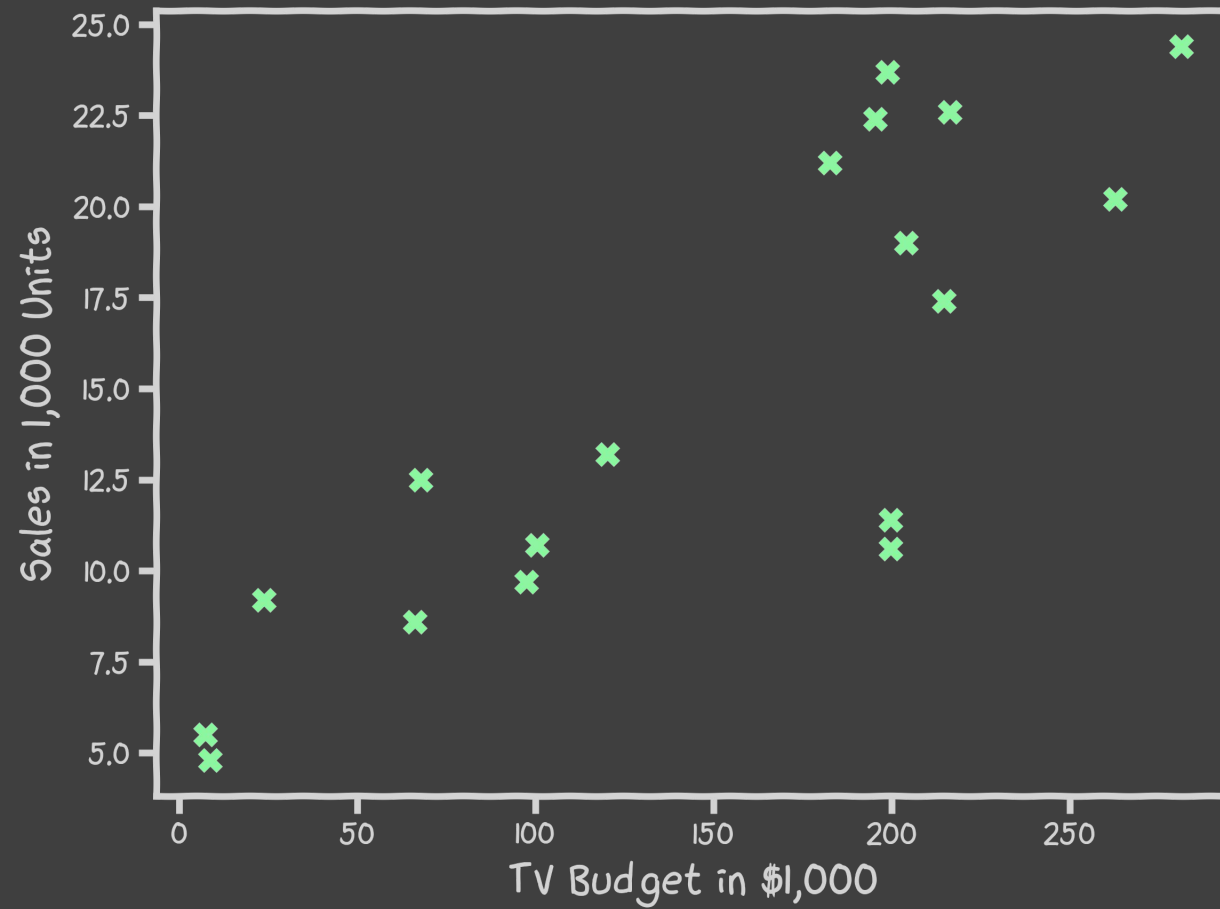

# Error Evaluation

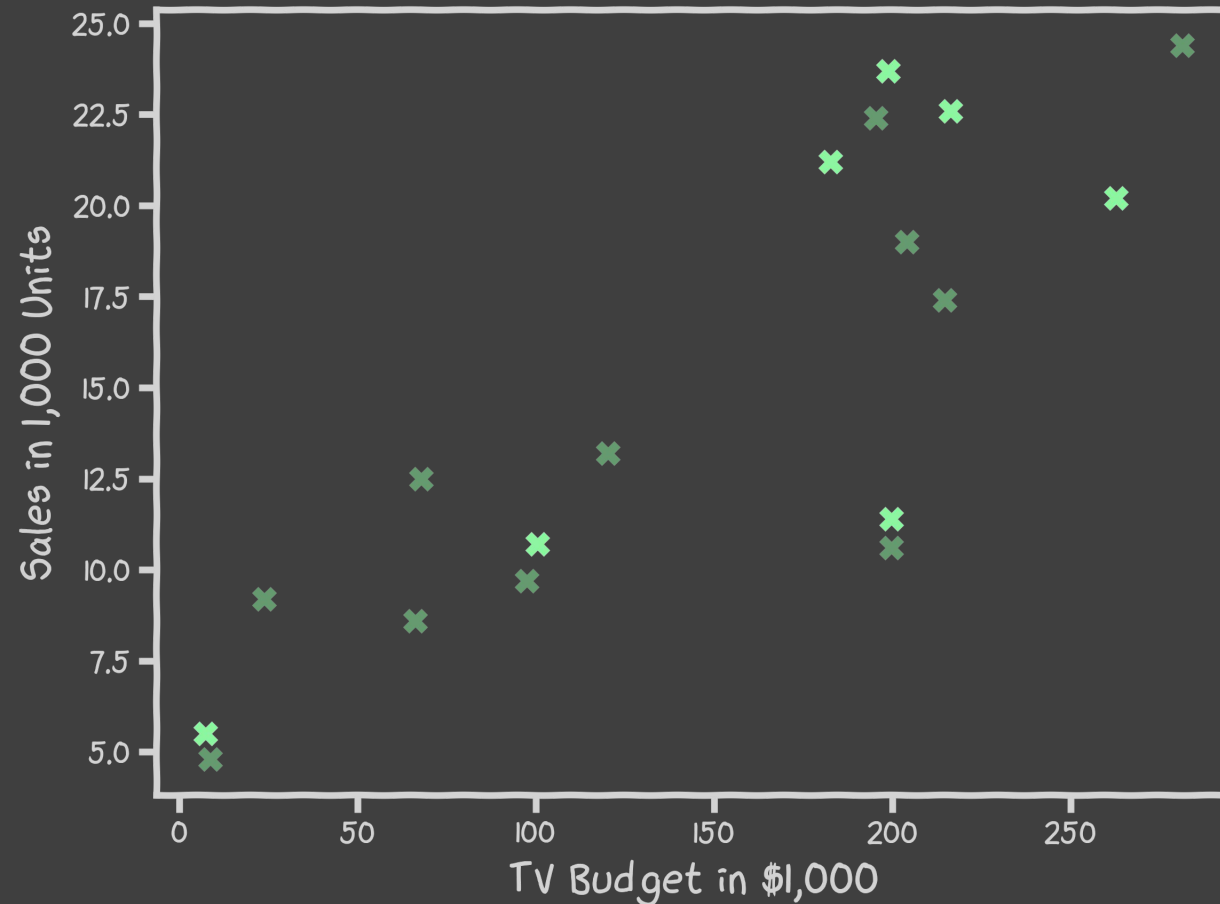

# Error Evaluation

Start with some data.

# Error Evaluation

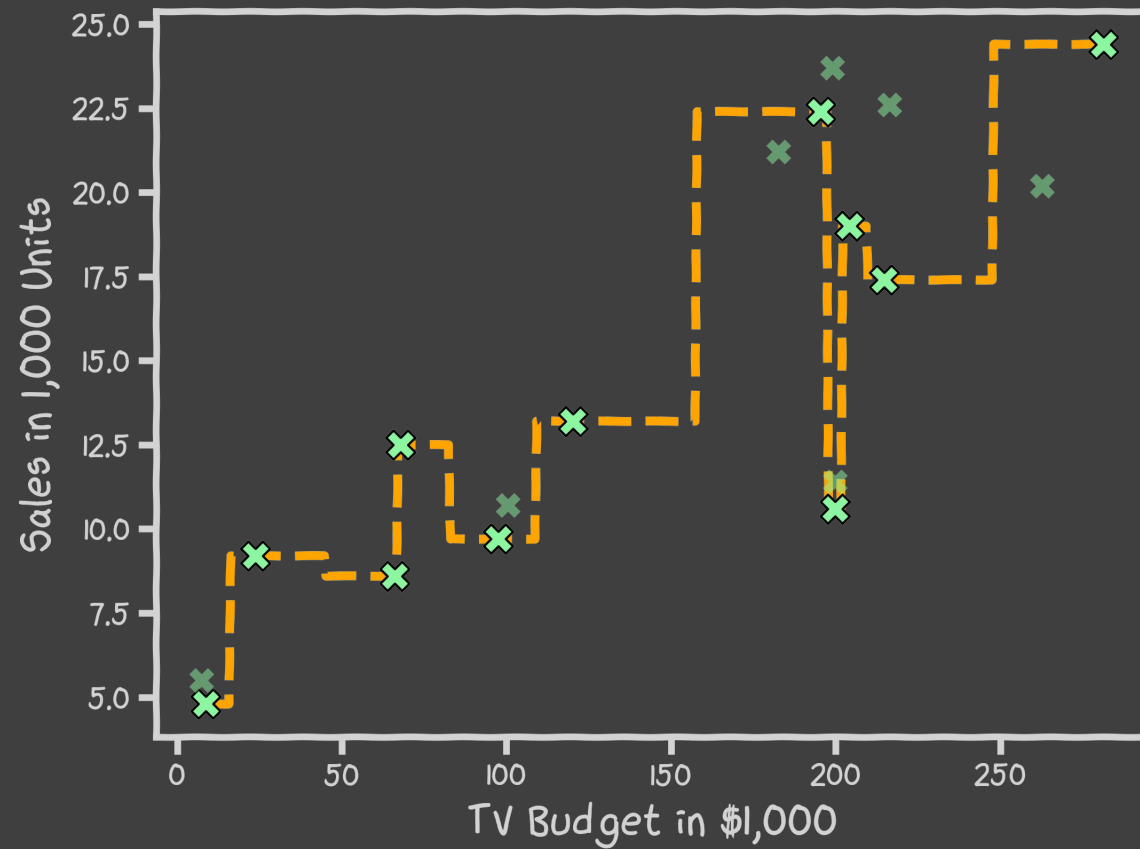

Randomly hide some of the data from the model. This is called **train-validation** split.

We use the train set to estimate  $\hat{y}$ , and the validation set to evaluate the model.

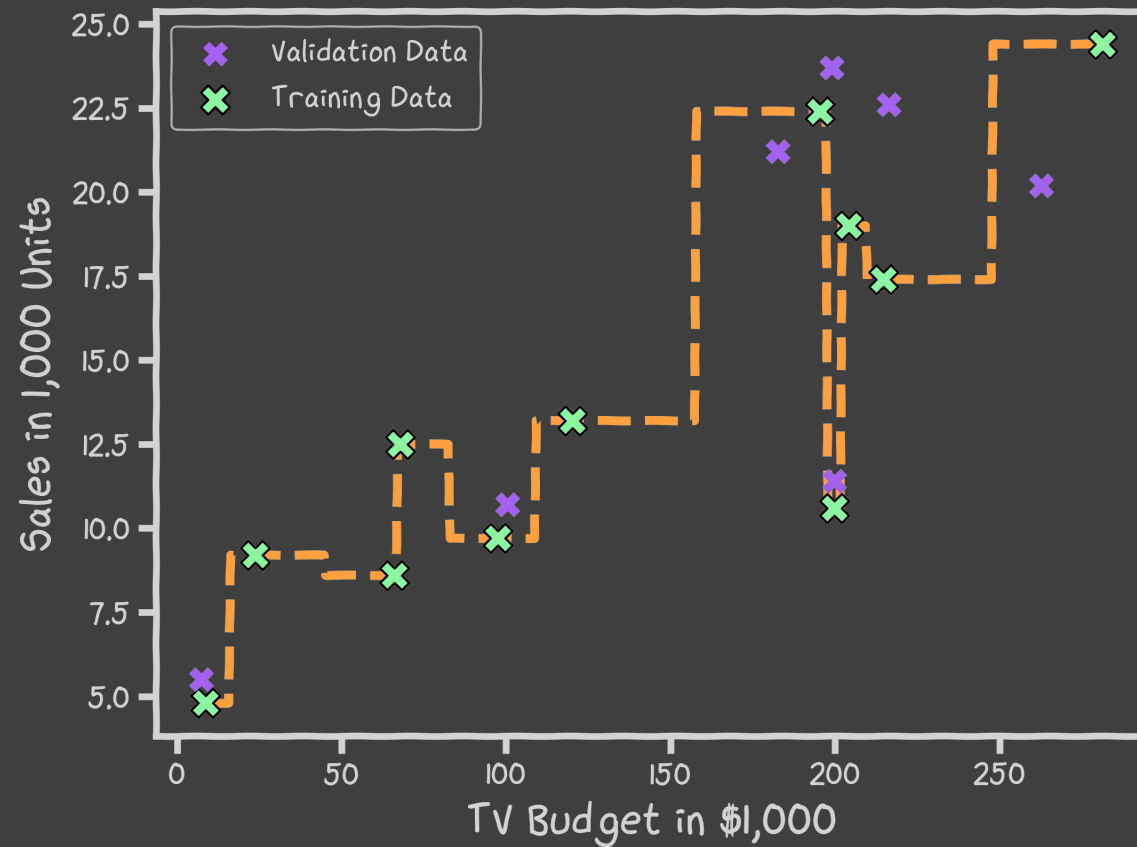

# Error Evaluation

Estimate  $\hat{y}$  for  $k=1$ .

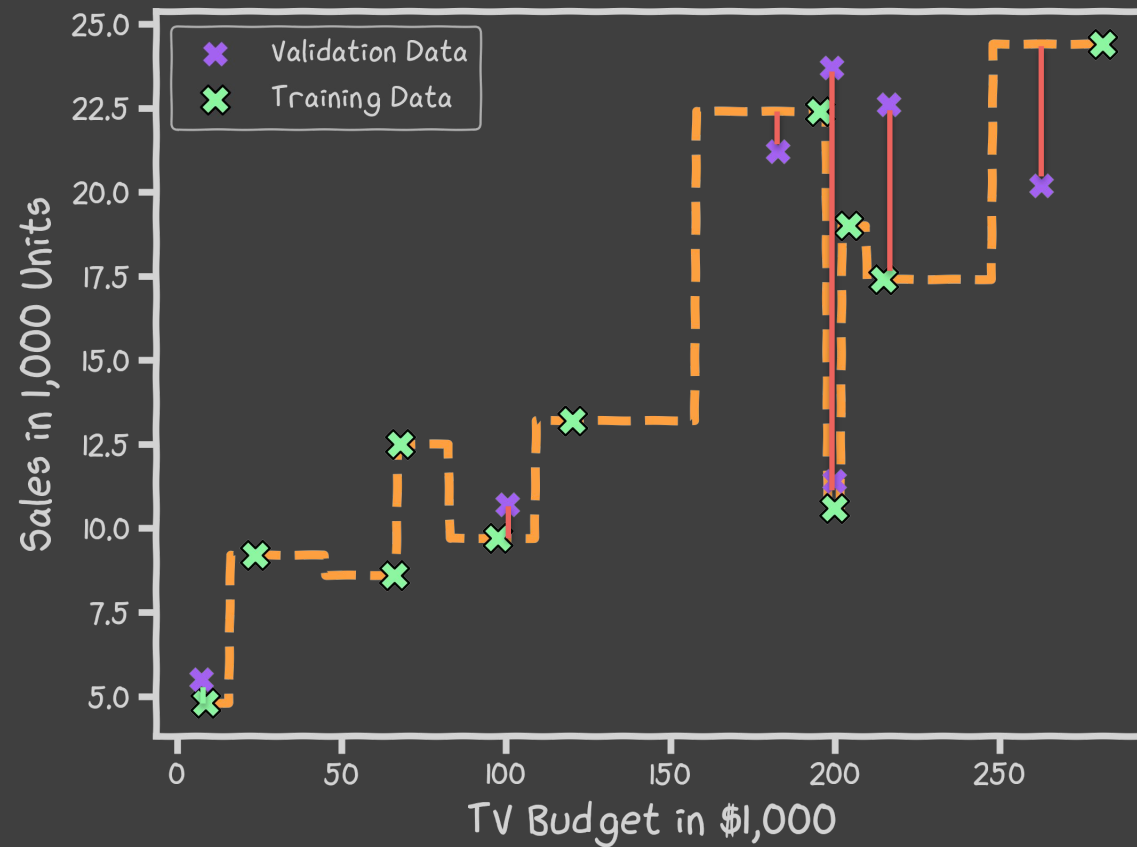

# Error Evaluation

Now, we look at the data we have not used, the **validation data** (red crosses).

# Error Evaluation

Calculate the residuals  $(y_i - \hat{y}_i)$ .

For each observation  $(x_n, y_n)$ , the absolute residuals,  $r_i = |y_i - \hat{y}_i|$  quantify the error at each observation.

In order to quantify how well a model performs, we aggregate the errors, and we call that the *loss* or *error* or *cost function*.

A common loss function for quantitative outcomes is the **Mean Squared Error (MSE)**:

$$MSE = \frac{1}{n} \sum_{i=1}^n (y_i - \hat{y}_i)^2$$

Note: Loss and cost function refer to the same thing. Cost usually refers to the total loss where loss refers to a single training point.

# Error Evaluation

**Caution:** The MSE is by no means the only valid (or the best) loss function!

Other choices for loss function:

1. Max Absolute Error
2. Mean Absolute Error
3. Mean Squared Error

**Note:** The square Root of the Mean of the Squared Errors (RMSE) is also commonly used.

$$RMSE = \sqrt{MSE} = \sqrt{\frac{1}{n} \sum_{i=1}^n (y_i - \hat{y}_i)^2}$$

# Error Evaluation

**Caution:** The MSE is by no means the only valid (or the best) loss function!

Other choices for loss function:

1. Max Absolute Error
2. Mean Absolute Error
3. Mean Squared Error

We will motivate MSE when we introduce probabilistic modeling.

**Note:** The square Root of the Mean of the Squared Errors (RMSE) is also commonly used.

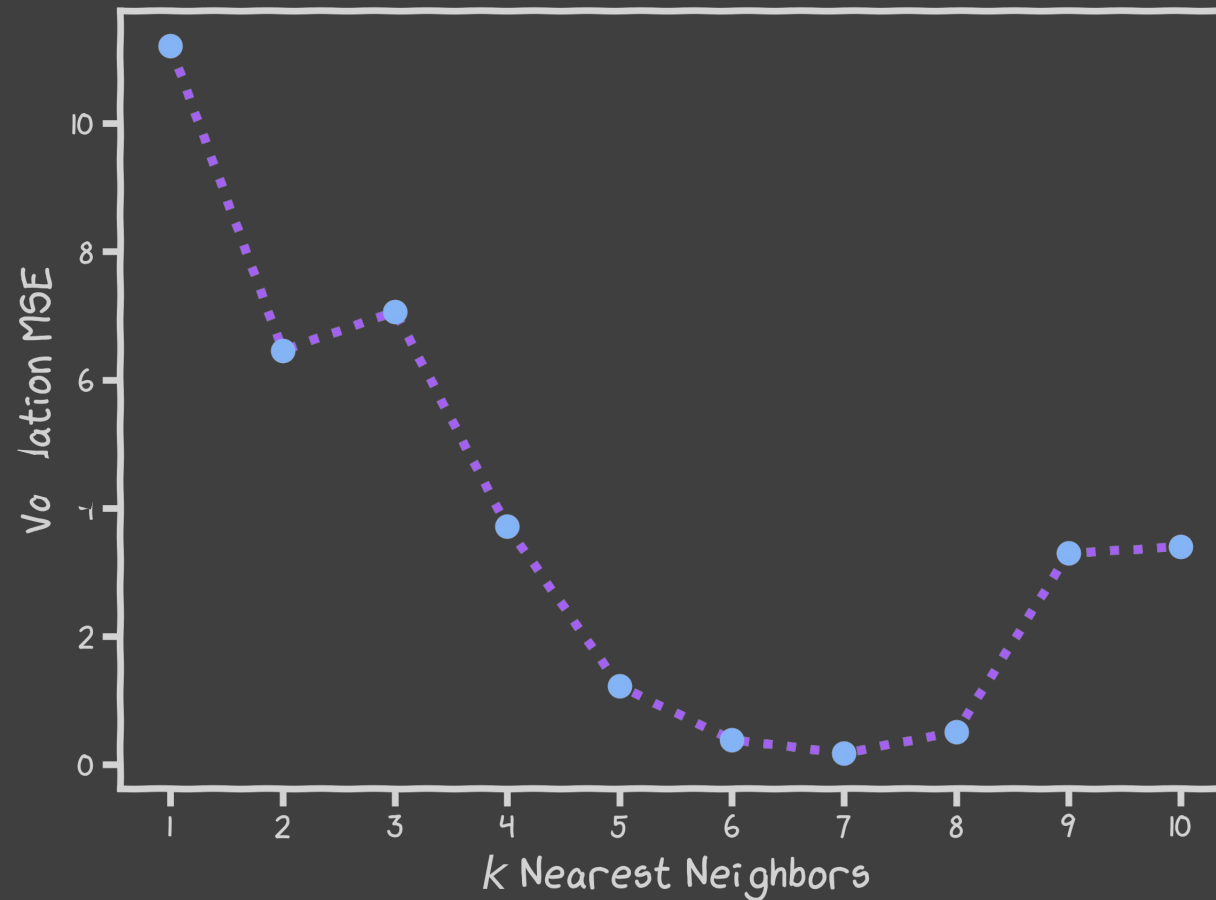

$$RMSE = \sqrt{MSE} = \sqrt{\frac{1}{n} \sum_{i=1}^n (y_i - \hat{y}_i)^2}$$

# Model Comparison

# Model Comparison

Do the same for all  $k$ 's and compare the MSEs.

Which model is the best?

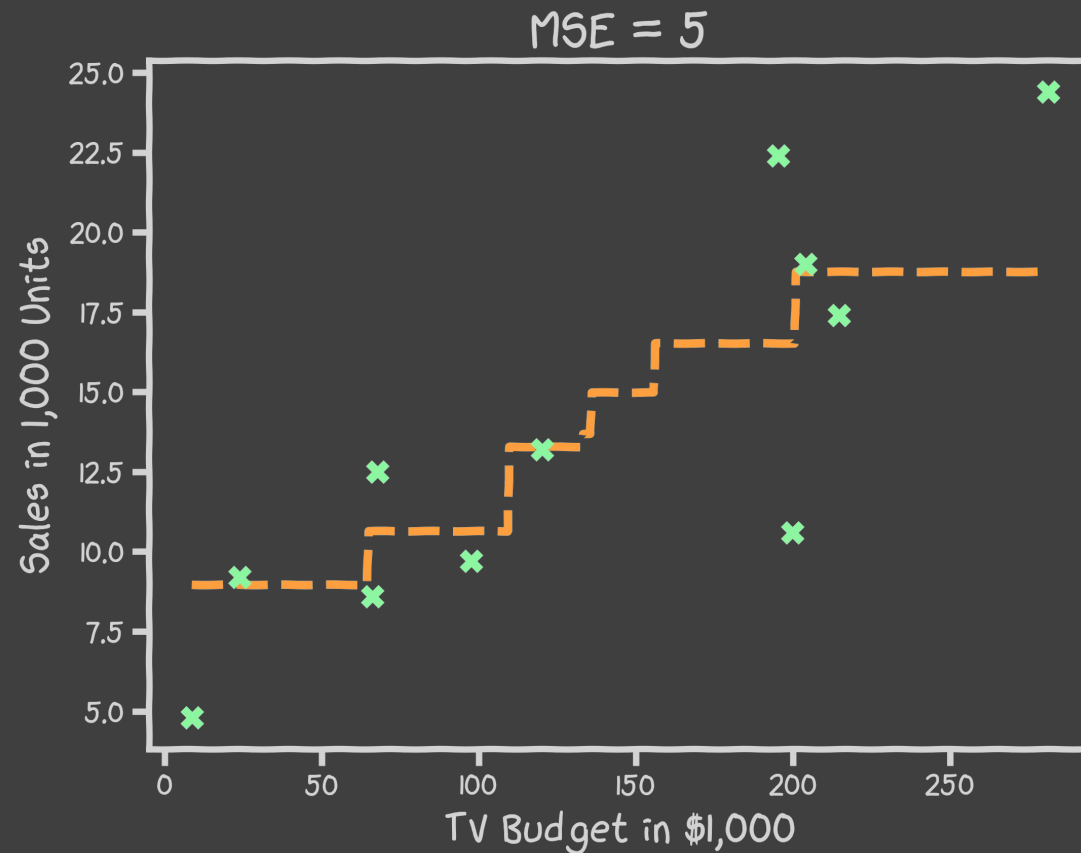

$k=7$  seems to be the **best model**.

# Model Fitness

# Model fitness

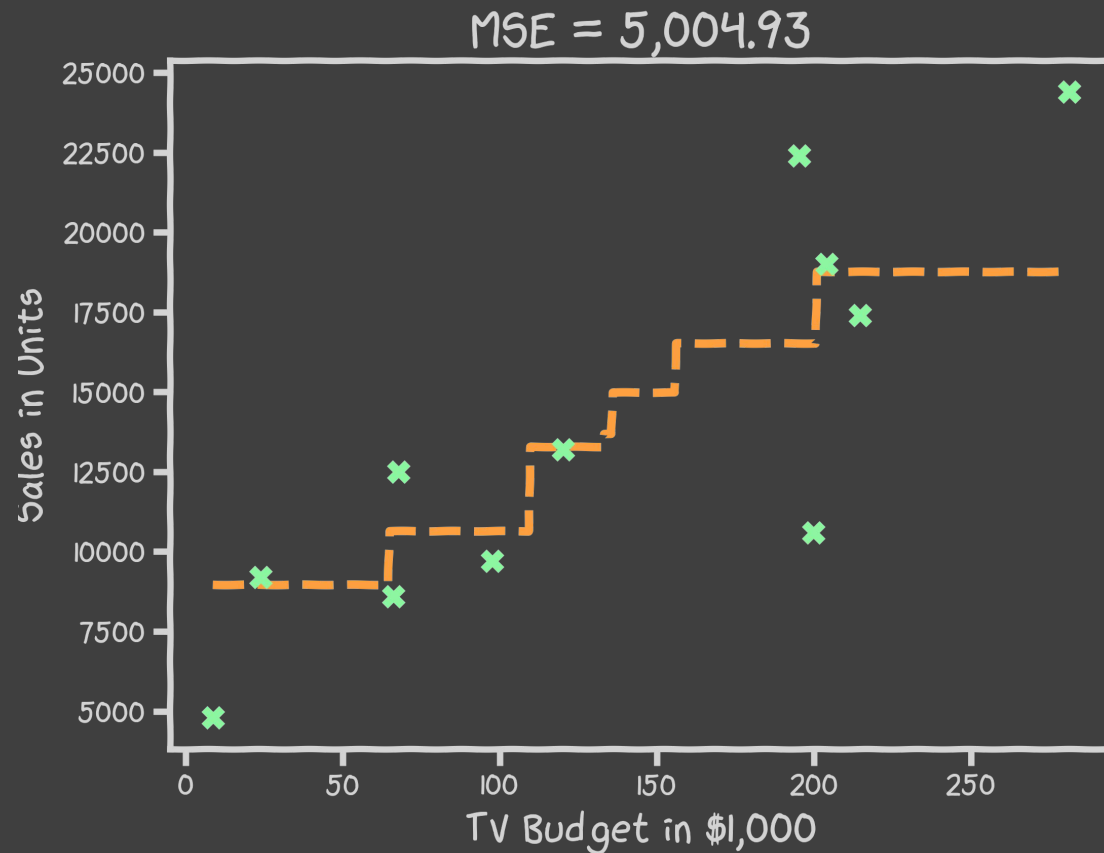

For a subset of the data, calculate the MSE for  $k=3$ .

Is  $MSE=5.0$  good enough?

# Model fitness

What if we measure the Sales in single units instead of thousands?

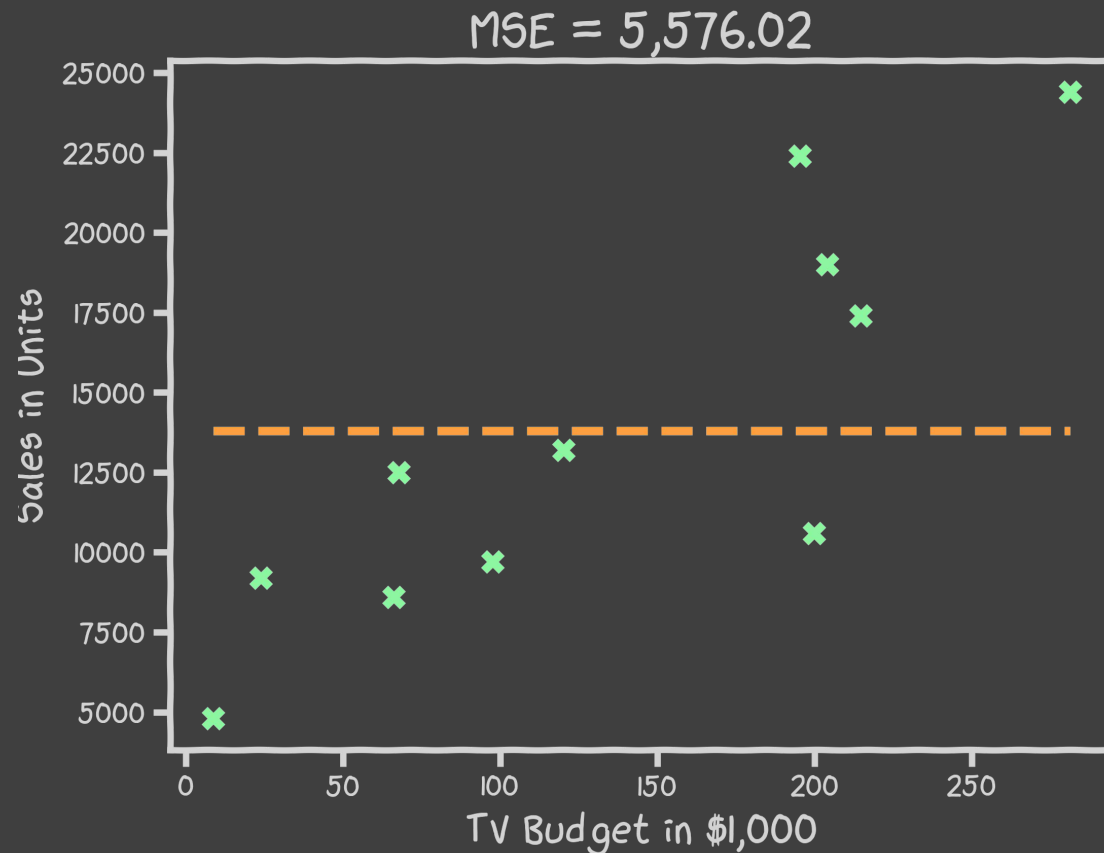

MSE is now 5004.93.

Is that good?

# Model fitness

It is better if we compare it to something.

We will use the simplest model:

$$\hat{y} = \bar{y} = \frac{1}{n} \sum_i y_i$$

as the worst possible model  
and

$$\hat{y}_i = y_i$$

as the best possible model.

# R-squared

Though is called  
R-squared, it is not the  
square of R

$$R - squared = 1 - \frac{\sum_i (\hat{y}_i - y_i)^2}{\sum_i (\bar{y} - y_i)^2}$$

- If our model is as good as the mean value,  $\bar{y}$ , then  $R - squared = 0$
- If our model is perfect, then  $R - squared = 1$
- $R^2$  can be negative if the model is worst than the average. This can happen when we evaluate the model in the validation set.
